Abstract

The disposition kinetic of tilmicosin (25mg/kg) was studied following oral administration alone, pretreated with amprolium (240 ppm), pretreated with diclazuril (2.5 ppm) and pretreated with toltrazuril (25 ppm) in broiler chickens. The serum tilmicosin concentrations were determined by microbiological assay technique using *Bacillus subtilis* (ATCC 6633) as the test organism. Following oral administration of tilmicosin, the disposition curve was best described by two-compartment open model. The maximum serum concentration (C_{max}) was 1.90 ± 0.11 , 1.27 ± 0.13 , 1.50 ± 0.14 and $1.41 \pm 0.11 \mu\text{g/ml}$ for tilmicosin alone and in the presence of amprolium, diclazuril and toltrazuril, respectively. The elimination half-life ($T_{0.5 (el)}$) was significantly decreased (5.28 ± 0.30 , 5.88 ± 0.33 , 6.03 ± 0.25 h, respectively) in amprolium, diclazuril and toltrazuril pretreated broiler chicken compared to tilmicosin alone (7.30 ± 0.41 h). The outcomes illustrated a significant decrease in the interval between doses in amprolium, diclazuril and toltrazuril pretreated broiler chicken compared to tilmicosin alone. Amprolium diclazuril and toltrazuril, resulted in a significance decrease in AUC (12.02 ± 1.14 , 15.50 ± 1.26 and $14.56 \pm 1.46 \mu\text{g.h.ml}^{-1}$, respectively) compared to tilmicosin alone ($21.98 \pm 1.83 \mu\text{g.h.ml}^{-1}$). It is concluded that the administration of amprolium, diclazuril and toltrazuril before tilmicosin would altered its pharmacokinetic profile in broiler chicken.

Keywords: Anticoccidials, Broiler Chickens, Kinetic, Tilmicosin.

1. Introduction

The attendant utilization of more than one drug is possible in the field of veterinary prescription exceptionally the poultry farm, for example the accompanying utilizing of anticoccidial, antibiotics, and growth promoters, at the same time to overcome diseases (Jones and Ricke 2003). The accompanying utilization of various medications with each other may result in drug-drug interactions. Drug-drug interactions may prompt changes in the concentrations of drug in the body, which may exaggerate or impair the proposed viability of the antibiotics utilized for treatment of bacterial diseases.

The macrolide is a group of compounds which comparable in the structure, the vast majority of which are gotten from numerous types of Streptomyces soil-borne bacteria (Scott et al. 1996). Macrolides are effective against Gram-positive bacteria, such as Streptococcus spp. what's more, Staphylococcus spp., Mycoplasma spp, however are marginally successful against Gram-negative living beings (Botsolou and Fletouris 2001). Tilmicosin is a bacteriostatic macrolide antibiotic got from tylosin for veterinary use only. It is predominantly viable against Mycoplasma spp., Pasteurella spp., and many Gram-positive bacteria with viability against anaerobic bacteria and some Gram-negative respiratory bacteria such as Pasteurella multocida and Mannheimia haemolytica (Prescott 2000). In poultry farm, tilmicosin utilized for respiratory tract contaminations treatment which caused by Mycoplasma synoviae, Mycoplasma gallisepticum, Pasteurella multocida and Ornithobacterium rhinotracheale (Kempf et al. 1997; Abu-Basha et al. 2007). Amprolium is a thiamine analogue, which is broadly utilized as a part of coccidiosis in poultry and rabbit's farms (McDougald and Reid 1997). It may interact with any administered drugs, as it is

normally added as a food added substance to poultry rations. Toltrazuril is a triazinetrione derivative. It is expected for the avoidance and treatment of coccidiosis in chickens and turkeys (Vertommen et al. 1990). Diclazuril chemically, 2-(4-Chlorophenyl)-2- [2, 6-dichloro-4-(3, 5-dioxo-1, 2, 4-triazin-2-yl) phenyl] acetonitrile, is a potent anticoccidial drug. The utilizing of diclazuril is broadly as a part of most animal varieties including chickens, turkeys, cattle, and pigs for treatment and counteractive action of coccidiosis (Taylor et al. 2003).

The point of this study is to examine the impact of amprolium, diclazuril and toltrazuril pretreatment on the pharmacokinetics of tilmicosin following a single oral administration in broiler chickens.

2. Materials and methods

2.1. Drug

Tilmicosin was obtained as an oral solution under trade name (Tilmosol 25%)[®] from Arab Company for Medical Products (ARABCOMED). Each 100 ml contains tilmicosin phosphate 28 gm equivalent to tilmicosin base 25 gm. Amprolium was obtained as water soluble powder under trade name (Amprolium 20%)[®] from Adwia company. Diclazuril was obtained as oral solution under trade name (Diclosol)[®] from Pharma-Swede Egypt company. Toltrazuril was obtained as oral solution under trade name (Primacox 2.5%)[®] from Primavet company.

2.2. Birds

Twenty-four clearly solid Hubbard broiler chickens of both genders weighing from 1100-1450 g were utilized as a part of this examination. Chickens were acquired from a private poultry farm, then housed in hygienic floor system and were sustained on adjusted antimicrobial free ration. Water was offered not obligatory. Prior to the begin of investigations, chickens were watched for 2 weeks to ensure that their bodies are free from any anti-bacterial substances. The investigation was performed as per the rules set by the Ethical Committee of El-Sadat city University, Egypt.

2.3. Experimental design

Four principle groups of 6 chickens each were utilized. Birds of the 1st group were left as control group while those in the 2nd, 3rd and 4th groups were pretreated with amprolium (240 ppm) for 5 consecutive days, diclazuril (2.5 ppm) for 2 consecutive days and toltrazuril (25 ppm) for 2 consecutive days, respectively. After the last dose by 2 hours (to ensure that amprolium, diclazuril and toltrazuril reach its maximum serum concentration), each chicken in all groups was orally administered 25mg/kg BW of tilmicosin. Blood samples were collected from the right wing vein of each bird at 10, 20 and 30 minutes and 1, 2, 4, 6, 8, 12 and 24 hours. All blood samples were collected in sterilized centrifuged tubes and allowed to clot. Serum was separated by centrifugation at 3000 r.p.m for 10 minutes. Sera were kept frozen until assayed.

2.4. Drug bioassay

Tilmicosin in blood samples was assayed using microbiological method of antibiotic using *Bacillus subtilis* (ATCC 6633) as a test organism (Arret et al. 1971). Standard curves were constructed using antibacterial free serum collected from chicken and phosphate buffer. Six wells, 8mm in diameter, were cut at equal distances in standard Petri dishes containing 25mL seeded agar. The wells were filled with 100 μ L of either the test samples tilmicosin standards. The plates were kept at room temperature for 2 h before being incubated at 37°C for 18 h. Zones of inhibition were measured using micrometers, and tilmicosin concentrations in the test samples were calculated from the standard curve.

The standard curve in chicken serum was linear over the range of 0.097 to 25 μ g/ml and the value of correlation coefficient (r) was

0.78. The limit of quantification was 0.097 μ g/ml. Protein binding of tilmicosin was estimated according to (Craig and Suh 1991). This method was based on the diffusion of free antibiotic into the agar medium. To estimate the protein binding of tilmicosin, the drug was dissolved in phosphate buffer and antibiotic free chicken's serum at different concentrations. This estimation was based on the facts that free unbound part of tilmicosin only capable to diffuse through agar. The differences in the diameters of the inhibition zones between the solutions of the drug in the phosphate buffer and serum samples were then calculated according to the following equation:

Protein binding % =

$$\frac{\text{Zone of inhibition in buffer} - \text{Zone of inhibition in serum}}{\text{Zone of inhibition in buffer}} \times 100$$

2.5. Pharmacokinetic analysis

Serum concentrations of tilmicosin for each individual chicken after oral administrations were subjected to a compartmental investigation utilizing a nonlinear least-squares regression analysis with the assistance of a computerized curve-stripping program (R Strip; Micromath Scientific Software, Salt Lake City, UT, USA). For PO data, the appropriate pharmacokinetic model was controlled by visual examination of individual concentration-time curves and by application of Akaike's Information Criterion (AIC) Yamaoka et al. 1978. The pharmacokinetic parameters were reported as mean \pm SD. Information acquired all through the study were investigated utilizing Students t-test (Snedecor and Cochran 1976).

3. Results

In the present study, all chickens were clearly sound amid the time of investigation and all medications were well tolerated. The serum tilmicosin concentrations following its oral administration alone, pretreated with amprolium, pretreated with diclazuril and pretreated with toltrazuril were incorporated in figure (1). The semi logarithmic serum concentration-time curve of tilmicosin in broilers, after oral administration of 25 mg/kg b.wt showed that the drug complied with a two-compartment open model.

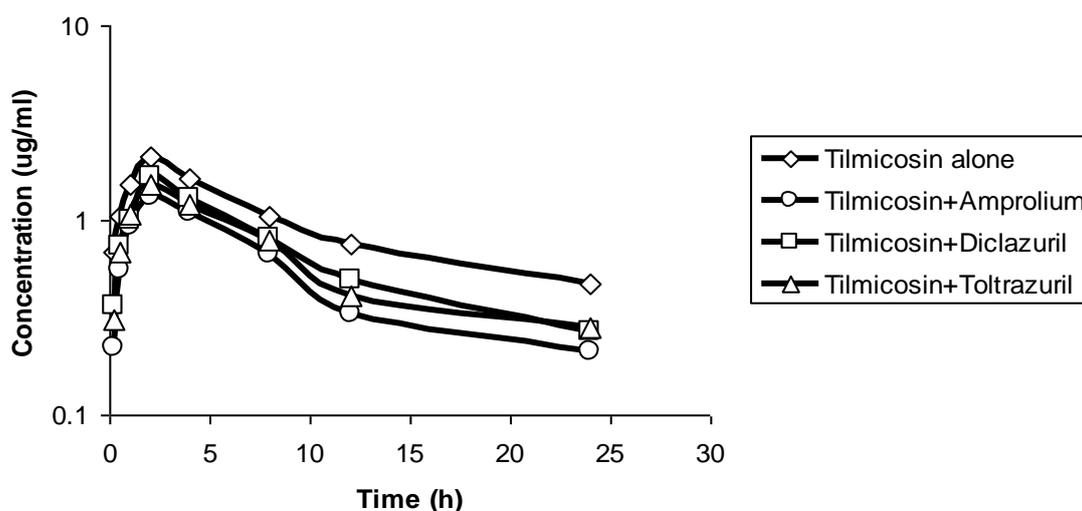

Fig. 1: Semi-Logarithmic Graph Depicting the Time Course of Tilmicosin In Broilers after A Single Oral Administration of 25 Mg/Kg.B.Wt. Alone, Pretreated with Amprolium Orally at A Dose Rate of 240 Ppm, Pretreated with Diclazuril Orally at A Dose Rate Of 2.5ppm and Pretreated with Toltrazuril Orally at A Dose Rate of 25ppm. (N=6).

Tilmicosin was firstly identified in serum 15 minutes following its oral administration. The mean top serum level ($1.90 \pm 0.11 \mu$ g/ml) was accomplished at time (T_{max}) 2.13 ± 0.19 h post administration. The tilmicosin was still identified above MIC up to 24 h after administration alone or pretreated with amprolium, diclazuril and

toltrazuril. No tilmicosin could be detected thereafter. The acquired information revealed that the serum tilmicosin concentrations was decreased significantly at various time intervals in amprolium, diclazuril and toltrazuril pretreated broiler chickens compared to values recorded in tilmicosin alone.

The pharmacokinetic parameters of tilmicosin taking after its oral administration alone, pretreated with amprolium, pretreated with diclazuril and pretreated with toltrazuril were recorded in table (1). The acquired results demonstrated that the in vitro protein binding

tendency of tilmicosin to broiler chicken serum protein was $14.79 \pm 1.18\%$. This finding showed that the drug is somewhat bound to serum protein.

Table 1: Mean pharmacokinetic parameters of tilmicosin in broilers after a single oral administration of 25 mg/kg.b.wt. Alone, pretreated with amprolium orally at a dose rate of 240 ppm, pretreated with diclazuril orally at a dose rate of 2.5 ppm and pretreated with toltrazuril orally at a dose rate of 25 ppm. (n=6).

4. Discussion

After intravenous administration of tilmicosin in broiler chicken, cardiovascular toxicity and deaths have been mentioned by (Main et al. 1996; Papich and Riviere 2001). For this reason, I cannot calculate the bioavailability of tilmicosin in my study.

Following oral administration of tilmicosin in broiler chicken (25 mg/kg), the outcomes demonstrated that serum tilmicosin fixation versus time complied with a two-compartments open model which show the presence of two stages (circulation and disposal) stages. This outcome is like the outcome recorded for tilmicosin in swine (Shen et al. 2005). The maximum serum concentration of tilmicosin after oral administration was $1.90 \pm 0.11 \mu g/ml$. This finding was coordinating with that recorded for tilmicosin in chicken $2.09 \pm 0.37 \mu g/ml$ (Abu-Basha et al. 2007), while this quality was higher than reported in swine $1.19 \pm 0.30 \mu g/ml$ (Shen et al. 2005). On the other hand, time to peak serum concentration was 2.13 ± 0.19 h. This outcome was near that recorded for tylosin in chicken 2.36 ± 0.42 h (Abu-Basha et al. 2012). While it was shorter than the result recorded for tilmicosin in chicken 3.99 ± 0.84 h (Abu-Basha et al. 2007). In this study, the calculated AUC₍₀₋₂₄₎ was observed to be $21.98 \pm 1.83 \mu g \cdot h \cdot ml^{-1}$. The got result is like that recorded for tilmicosin in chicken $21.82 \pm 3.14 \mu g \cdot h \cdot ml^{-1}$ (Abu-Basha et al. 2007) and for tylosin in broiler chicken $18.60 \pm 1.50 \mu g \cdot h \cdot ml^{-1}$ (Soliman and Sedek 2016). In any case, the Area under serum concentration-time curve reported in this study is higher than rates reported in pig $9.68 \pm 0.91 \mu g \cdot h \cdot ml^{-1}$ (Dimitrova et al. 2011). Such contrasts are regular and habitually identified with interspecies variety, examine strategies utilized, age, breed and wellbeing status of the creature, and the plan of the medication utilized (Haddad et al. 1985).

The elimination half-life ($t_{0.5e}$) was 7.30 ± 0.41 h. These outcomes are reliable with those recorded for tylosin in broiler chickens (Soliman and Sedek 2016). However, it was longer than the outcome recorded for tylosin in chickens (Abu-Basha et al. 2012). These varieties may be credited to species contrasts, solid status and the measurement controlled for every situation.

One of the points of this study was to figure out whether there is a pharmacokinetic connection amongst tilmicosin and three anticoccidial in broiler chickens. Taking after oral administration, the mean serum concentrations of tilmicosin were significantly lower in amprolium, diclazuril and toltrazuril pretreated broiler chicken contrasted with tilmicosin alone. Comparative discoveries were already reported for amprolium and toltrazuril with levofloxacin in broilers (El-Banna et al. 2013). Additionally, this outcome was in concurring with that recorded for amprolium with amoxicillin in broiler chicken and for amprolium with lincomycin in broiler

chicken (El-Sayed et al. 2014 and El-Sayed et al. 2015), respectively.

The significance diminishes in C_{max} of tilmicosin when pretreated with amprolium, diclazuril or toltrazuril in broilers could be clarified on the premise of the impact of amprolium, diclazuril and toltrazuril on microsomal catalysts of liver. In this appreciation, comparative perception was beforehand reported by Abo El-Sooud (2003) on co-administration of enrofloxacin with albendazole in goats. Both albendazole and toltrazuril are profoundly metabolized to sulphone in liver (Brander et al. 1991), a phenomenon which could clarify the plausible comparability of both medications in impelling CYP 450 catalysts in creatures and flying creatures and hence the quick digestion system and lower C_{max} of tilmicosin. Pretreatment of chickens with toltrazuril two days before tilmicosin administration is sufficient time to prompt liver microsomal CYP 450 proteins, in spite of the fact that Abo El-Sooud (2003) found that a single dose of albendazole was adequate to affect such induction in goats. Moreover, this result was in agreeing with that recorded by (Atef et al. 2010) who found that goats pre-treated with radoxanide or albendazole demonstrated a significant decline in serum flufenicol level when contrasted with non-anthelmintic treated goats.

Amprolium, diclazuril and toltrazuril brought about a significance diminish in the elimination half-life and the area under serum concentration-time curve contrasted with tilmicosin alone. Comparative discoveries were already reported for amprolium and toltrazuril with levofloxacin in broilers (El-Banna et al. 2013). This result was in agreeing with that recorded for diclazuril with tylosin in broiler chicken (Atef et al. 2009). The interval between doses demonstrated lower values in amprolium, diclazuril and toltrazuril pretreated broiler chicken appeared differently in relation to tilmicosin alone. Similar disclosures were at that point reported for amprolium and toltrazuril with levofloxacin in broilers (El-Banna et al. 2013).

5. Conclusion

It is reasoned that administration of amprolium, diclazuril and toltrazuril before tilmicosin in broiler chickens would altered its kinetic profiles of oral tilmicosin. Therefore, under this condition, the dose of tilmicosin administration by oral route needs to be deliberately balanced.

6. Conflict of interests

The author declares that there is no conflict of interests regarding the publication of this article.
